

Optimal Execution:

III. Game Theory & Predatory Trading

René Carmona

Premises for Predatory Trading

- ▶ Large Trader facing a Forced Liquidation
- ▶ Especially if the need to liquidate is known by other traders
 - ▶ hedge funds with (nearing) margin call
 - ▶ traders who use portfolio insurance, stop loss orders, . . .
 - ▶ some institutions / funds cannot hold on to downgraded instruments
 - ▶ Index-replication funds (at re-balancing dates) e.g. Russell 3000

Forced liquidation can be **very costly** because of **price impact**

Business Week

...if lenders know that a hedge fund needs to sell something quickly, they will sell the same asset, driving the price down even faster. Goldman Sachs and other counter-parties to LTCM did exactly that in 1998.

When you smell blood in the water, you become a shark . . . when you know that one of your number is in trouble . . . you try to figure out what he owns and you start shorting those stocks . . .

Cramer (2002)

Typical Predatory Trading Scenario

- ▶ Distressed trader needs to unload a large position
- ▶ Size will have impact on price
- ▶ Predator initially trades in the same direction as the prey
- ▶ Effect is to withdraw liquidity
- ▶ Market impact of the liquidation becomes greater
- ▶ Price fall is exaggerated (**over-shooting**)
- ▶ Predator reverses direction, profiting from the over-shoot
- ▶ Predator closes position for a profit.

Optimal Portfolio Liquidation: Multi-Player Case

- ▶ New issues when other market participants know that our client is selling:
- ▶ The market impact of our client creates a drift in the market price
- ▶ This drift can be exploited by the other market participants
- ▶ Since we know about this danger, we will adjust our strategy
 - ▶ Brunnermeier and Pedersen (2005),
 - ▶ Carlin, Lobo, and Viswanathan (2005)
 - ▶ Schied, Schöneborn (2008)

Game Model

- ▶ One risk free asset and one risky asset
- ▶ Trading in continuous time, interest rate $r = 0$
- ▶ $n + 1$ strategic players and a number of noise traders
- ▶ $X_0(t), X_1(t), \dots, X_n(t)$ risky asset positions of the strategic players
- ▶ Trades at time t are executed at the price (**Chriss-Almgren price impact model**)

$$P(t) = \tilde{P}(t) + \gamma \sum_{i=0}^n [X_i(t) - X_i(0)] + \lambda \sum_{i=0}^n \dot{X}_i(t)$$

where $\tilde{P}(t)$ is a **mean zero** martingale (say a Wiener process).

Goal of the Mathematical Analysis

- ▶ Understand predation
- ▶ Illustrate benefits of
 - ▶ Stealth trading
 - ▶ Sunshine trading

Modeling extreme markets

- ▶ **Elastic** (truly illiquid) markets:
 - ▶ temporary impact $\lambda \gg$ permanent impact γ
- ▶ **Plastic** (nervous) markets:
 - ▶ permanent impact $\gamma \gg$ temporary impact λ

Assumptions of the One Period Game

- ▶ Each strategic player $i \in \{0, 1, \dots, n\}$ knows
 - ▶ all other strategic players initial asset positions $X^j(0)$
 - ▶ Their target $X_j(T)$ at some fixed time point $T > 0$ in the future
- ▶ Objective (all players are **risk neutral**)
 - ▶ Players maximize their expected return by choosing an optimal trading strategy $X_i(t)$ satisfying their constraints $X_i(0)$ and $X_i(T)$

One **distressed trader / prey** (e.g **seller**), player 0

$$X_0(0) = x_0 > 0, \quad X_0(T) = 0$$

n **predators** players $1, 2, \dots, n$

$$X_i(0) = X_i(T) = 0, \quad i = 1, \dots, n$$

Optimization Problem

A strategy $X_i = (X_i(t))_{0 \leq t \leq T}$ is **admissible** (for player i) if it is an a

- ▶ adapted process
- ▶ with continuously differentiable sample paths

Given a set $\underline{X} = (X_0, X_1, \dots, X_n)$ of admissible strategies

- ▶ Each player $i \in \{0, 1, \dots, n\}$ tries to maximize his expected return

$$J^i(\underline{X}) = \mathbb{E} \left[\int_0^T (-\dot{X}_i(t)) P(t) dt \right]$$

under the constraint

$$P(t) = \tilde{P}(t) + \gamma \sum_{i=0}^n [X_i(t) - X_i(0)] + \lambda \sum_{i=0}^n \dot{X}_i(t)$$

- ▶ Search for **Nash Equilibrium**

Deterministic Strategies

If we restrict the admissible strategies $\underline{X} = (X_0, X_1, \dots, X_n)$ to be **DETERMINISTIC**

$$J^i(\underline{X}) = \mathbb{E}\left[\int_0^T (-\dot{X}_i(t))P(t)dt\right] = \mathbb{E}\left[\int_0^T (-\dot{X}_i(t))\bar{P}(t)dt\right]$$

where

$$\bar{P}(t) = P(0) + \gamma \sum_{i=0}^n [X_i(t) - X_i(0)] + \lambda \sum_{i=0}^n \dot{X}_i(t)$$

THE SOURCE OF RANDOMNESS IS GONE !

Carlin, Lobo, and Viswanathan (2005) Schied, Schoenborn (2008)

Solution in the Deterministic Case

Unique Optimal Strategies

$$X_i(t) = ae^{-\frac{n}{n+2} \frac{\gamma}{\lambda} t} + b_i e^{\frac{\gamma}{\lambda} t}$$

where

$$a = \frac{n}{n+2} \frac{\gamma}{\lambda} \left(1 - e^{-\frac{n}{n+2} \frac{\gamma}{\lambda} T}\right)^{-1} \frac{1}{n+1} \sum_{i=0}^n [X_i(T) - X_i(0)]$$

$$b_i = \frac{\gamma}{\lambda} \left(e^{\frac{\gamma}{\lambda} T} - 1\right)^{-1} \left(X_i(T) - X_i(0) - \frac{1}{n+1} \sum_{i=0}^n [X_i(T) - X_i(0)]\right)$$

Carlin, Lobo, and Viswanathan (2005)

$n = 1$ predator, $\gamma/\lambda = 0.3$

Holdings of **Distressed Trader** & **Predator**

$n = 1$ predator, $\gamma = \lambda$

Holdings of **Distressed Trader** & **Predator**

$n = 1$ predator, $\gamma = 15.5\lambda$

Holdings of **Distressed Trader** & **Predator**

Holdings of the Distressed Trader & Predator

Fancy Plots of the Holdings of the Distressed Trader & Predator

Impact of the Number of Predators: $\gamma = \lambda$

Holdings of Distressed Trader & 1 Predator

Holdings of Distressed Trader & 50 Predators

Impact of the Number of Predators: $\gamma = 15.5\lambda$

Holdings of Distressed Trader & 1 Predator

Holdings of Distressed Trader & 50 Predators

Expected Price: $\gamma = \lambda$

Expected Price for 1 Predator

Expected Price for 50 Predators

Expected Price: $\gamma = 15\lambda$

Expected Price for 1 Predator

Expected Price for 50 Predators

Impact of Nb of Predators on Expected Returns

Expected Returns of Distressed Trader GOL=1 & GOL=15

Expected Returns of Predators GOL=1 & GOL=15

Two Period Model

- ▶ Prey has to liquidate $X_0 > 0$ by time T_1 , i.e. $X_0(T_1) = 0$
- ▶ Predators can stay in the game longer $X_i(0) = X_i(T_2) = 0$ for some $T_2 > T_1$ for $i = 1, \dots, n$
- ▶ Prey does not trade in second period $[T_1, T_2]$, i.e. $X_0(t) = 0$ for $T_1 \leq t \leq T_2$.

Markovian Structure \implies

Solution determined by predators' positions at time T_1

Nash Equilibrium for Deterministic Strategies

UNIQUE Nash Equilibrium

- ▶ **ALL** Predators have the same position at time T_1

$$X_i(T_1) = \frac{A_2 n^2 + A_1 n + A_0}{B_3 n^3 + B_2 n^2 + B_1 n + B_0} X_0, \quad i = 1, \dots, n$$

- ▶ Coefficients depend upon n but converge as $n \rightarrow \infty$
- ▶ Asymptotic formulas for expected returns
- ▶ Asymptotic comparison of **Stealth** versus Sunshine trading for some regimes of γ/λ

Schöneborn - Schied (2008)
